Masters in Medical Bioinformatics  
academic year 2017/18, spring term

### Strings and Sequences in Biology

## Strings in molecular biology

Strings are finite sequences over an alphabet  $\Sigma$  (also called *sequences*).

- DNA (characters: nucleotides)  $\Sigma = \{A, C, G, T\}$
- RNA (characters: nucleotides)  $\Sigma = \{A, C, G, U\}$
- proteins (characters: amino acids)  $\Sigma = \{A, C, D, E, F, \dots, W, Y\}$
- many other problems in molecular biology can be modelled by strings (e.g. gene order, SNPs, haplotypes, ...)

## DNA: nucleotides

5' ... AACAGTACCATGCTAGGTCAATCGA ... 3'  
3' ... TTGTCATGGTACGATCCAGTTAGCT ... 5'

- 4 characters: A C G T: adenine, cytosine, guanine, thymine (bases, nucleotides)
- orientation (read from 5' to 3' end)
- length measured in bp (base pairs)
- double stranded, the two strands are *antiparallel*
- A - T and C - G complementary (Watson-Crick pairs)
- reverse complement:  $(ACCTG)^{rc} = CAGGT$

## DNA: nucleotides

5' ... AACAGTACCATGCTAGGTCAATCGA ... 3'  
3' ... TTGTCATGGTACGATCCAGTTAGCT ... 5'

- during transcription, one strand is copied into mRNA (messenger RNA), except all T's are replaced by U's
- the strand which is identical to the mRNA is called *coding* strand
- the other strand (the one which is used for the transcription) is called *template* strand
- Both strands can be used as coding strands (for different genes).
- Some DNA strings are circular: bacterial DNA, mitochondrial DNA.

5 / 10

## RNA: nucleotides

- like DNA, except:
- 4 characters: A C U G: adenine, cytosine, uracil, guanine (U instead of T)
- RNA is single-stranded
- builds double stranded hybrids with DNA
- RNA folds upon itself (makes complex 3-dim structures), using the Watson-Crick pairs and other bonds (RNA folding)

## Protein: Amino acids

There are 20 common amino acids (aa's); two systems of abbreviations are used: 3-letter-code and 1-letter-code. We usually use the 1-letter-code.

alanine	Ala	A	leucine	Leu	L
arginine	Arg	R	lysine	Lys	K
asparagine	Asn	N	methionine	Met	M
aspartic acid	Asp	D	phenylalanine	Phe	F
cysteine	Cys	C	proline	Pro	P
glutamine	Gln	Q	serine	Ser	S
glutamic acid	Glu	E	threonine	Thr	T
glycine	Gly	G	tryptophan	Trp	W
histidine	His	H	tyrosine	Tyr	Y
isoleucine	Ile	I	valine	Val	V

## The genetic code

- standard genetic code (some organisms use a different one)
- 3 different reading frames for translation: The DNA sequence  
5' ...TATTCGAATCGGC...3'  
can be translated in 3 different ways, leading to different aa sequences.
- *degeneracy of the genetic code*
- silent mutations

## The genetic code

- standard genetic code (some organisms use a different one)
- 3 different reading frames for translation: The DNA sequence  
5' ...TATTCGAATCGGC...3'  
can be translated in 3 different ways, leading to different aa sequences.
- *degeneracy of the genetic code*: 64 codons but only 20 aa's plus stop codon
- silent mutations

9 / 10

## The genetic code

- standard genetic code (some organisms use a different one)
- 3 different reading frames for translation: The DNA sequence  
5' ...TATTCGAATCGGC...3'  
can be translated in 3 different ways, leading to different aa sequences.
- *degeneracy of the genetic code*: 64 codons but only 20 aa's plus stop codon
- silent mutations: if third position mutates, this often does not alter the aa

## The genetic code

### Exercise:

Translate this DNA sequence according to the 3 different reading frames:

5' ...TATTCGAATCGGC...3'
